

5.3i Graphing the Sine and Cosine Function part i

$$f(t) = \sin(t)$$

$t_1$	$f(t_1)$
0	
$\frac{\pi}{6}$	
$\frac{\pi}{4}$	
$\frac{\pi}{3}$	
$\frac{\pi}{2}$	

$t_1$	$f(t_1)$
$\pi$	
$\frac{3\pi}{2}$	
$2\pi$	

Note choice of scale on t axis.

Picture the unit circle. What happens to the \_\_\_\_\_ values as t increases from  $0 \rightarrow \pi/2$

What does y do as t goes from

$\pi/2 \rightarrow \pi$  \_\_\_\_\_

$\pi \rightarrow 3\pi/2$  \_\_\_\_\_

$3\pi/2 \rightarrow 2\pi$  \_\_\_\_\_

$2\pi \rightarrow 5\pi/2$  \_\_\_\_\_

## Unit 2: Trigonometric Functions and Introduction to Solving Trig Equations

A function is called periodic with period  $p$  if  $f(t+p) = f(t)$ . Since  $\sin(t+2\pi) = \sin(t)$ , the function  $f(t) = \sin(t)$  is \_\_\_\_\_ with period \_\_\_\_\_

How domain, range, period, even/odd, can be seen on graph.

This type of “sinusoidal wave” can be used to measure many physical phenomena.

Sin Cos and Tan animated from the unit circle

Author: Tim Eban  
Topic: Circle, Cosine, Sine, Trigonometry, Unit Circle

See how the functions sin, cos, and tan are defined from the unit circle, extending the definitions beyond the 0 to 90 degrees that fit nicely inside a right-angled triangle.

Using the graph to help visualize solutions to trig. Equations. As done in an earlier example. solve

$$\sin(t) = -\frac{\sqrt{2}}{2}$$

$$f(t) = \cos(t)$$

The graph of  $f(t) = \cos(t)$  can be generated similarly. In particular, plot the points corresponding to the quadrantal inputs (angles),

$t_1$	$f(t_1)$
0	
$\frac{\pi}{2}$	
$\pi$	
$\frac{3\pi}{2}$	
$2\pi$	

then using the unit circle, consider what \_\_\_\_\_ does as t goes from

$$0 \rightarrow \pi / 2$$

$$\pi / 2 \rightarrow \pi$$

$$\pi \rightarrow 3\pi / 2$$

$$3\pi / 2 \rightarrow 2\pi$$

$$2\pi \rightarrow 5\pi / 2$$

See the animation <https://www.geogebra.org/m/cNEtsbvC> again

**Note: On all Trigonometric graphs, it is expected that you show scale clearly and label coordinates of high points and low points on graph.**

Unit 2: Trigonometric Functions and Introduction to Solving Trig Equations

Both these graphs are \_\_\_\_\_ with period \_\_\_\_\_ and have key points occurring every quadrantal angle or every \_\_\_\_\_

Transformations of the sine and cosine graphs.

These two graphs can be used as basic graphs together with transformations (review 2.6 as needed).

$f(x) + c$

Vertical Shift

$f(x) - c$

Ex. Graph  $y =$  \_\_\_\_\_,  $y =$  \_\_\_\_\_

Ideally, eventually, rather than graph the original and then transform it, you would be able picture the transformation in your head to get a starting point, and then use the “quarter period pattern” to generate the rest.

$f(x+c)$

Horizontal Shift

$f(x-c)$

Ex. Graph  $f(t) = \cos(t - \pi/4)$

Ex. Graph  $f(t) = \cos(t + \pi/8)$

Maybe a better scale could be chosen ("zoom in")

Graph  $f(t) = \sin(t - \pi)$

Again, rather than graph the original and then transform it, picture the transformation in your head to get a starting point, and then use the “quarter period pattern” to generate the rest

When graphing a sine or cosine graph, a choice of scale showing multiples of is usually a good choice, but in some cases, a better choice can be made.

Graph  $y = \sin\left(t + \frac{\pi}{3}\right)$  \_\_\_\_\_

Combining Translations:

How would we graph  $y = \sin\left(t + \frac{\pi}{3}\right) + \frac{1}{2}$  ? \_\_\_\_\_

And ideally, without having to sketch the intermediate stages.

Note: At this point, as a convention, we switch our input from  $t$  to  $x$  but keep in mind, this  $x$  is not the same as the  $x$  value of the point on the unit circle.

For example:  $f(x) = \cos(x)$

Vertical Stretch/Compress and Reflection.  $y = c f(x)$

Ex. Graph  $f(x) = 2\cos(x)$

$f(x) = \frac{1}{2}\cos(x)$

Ex. Graph  $f(x) = -2\sin(x)$

And without drawing original graph:

In general, for graphs of the form:  $y = a \cos(t)$        $y = a \sin(t)$

5.3ii Graphing the Sine and Cosine Function part (period change)

Horizontal Stretch/Compress and Reflection.  $y = f(cx)$

Graph  $y = \sin(2x)$  \_\_\_\_\_

Initially, we might graph this by using our knowledge of horizontal compression or we might simply plot points (note: plotting points is inefficient and should be our last resource.)

Period? \_\_\_\_\_

Thus, the above graph is a horizontal compression whereas  $y = \sin\left(\frac{1}{3}x\right)$  is a horizontal stretch.

Period \_\_\_\_\_?

In general, for graphs of the form:  $y = \cos(kx)$        $y = \sin(kx)$

,

$k$  has the effect of changing the \_\_\_\_\_ to \_\_\_\_\_

For this type of graph, rather than sketch the original graph and then stretch/compress it, we plan ahead and find the period. Then we break this period into fourths since the key points (lo-zero-hi-zero) occur every one-fourth of the period, and choose our x axis scale accordingly.

*Reminder: On all Trigonometric graphs, it is expected that you show scale clearly and label coordinates of high points and low points on graph*

Unit 2: Trigonometric Functions and Introduction to Solving Trig Equations

Ex: Graph at least one period of \_\_\_\_\_

Ex: Graph at least one period of \_\_\_\_\_

Combining vertical and horizontal stretch/compress.

$$y = A\cos(kx)$$

$$y = A\sin(kx)$$

Ex:

This next example will lead us into the third part of graphing sine and cosine where we put it all together.

Graph  $f(x) = 4\sin(2x)$

Use the above graph to graph  $g(x) = 4\sin\left(2\left(x - \frac{\pi}{4}\right)\right)$

5.3ii Graphing the Sine and Cosine Function part iii : Putting it All Together

Use the graph of  $f(x) = 4\sin(2x)$  to graph  $g(x) = 4\sin\left(2\left(x - \frac{\pi}{4}\right)\right)$

Notice, the function  $g(x)$  would normally be written \_\_\_\_\_

But what was the horizontal shift? \_\_\_\_\_

Note: The horizontal shift is NOT \_\_\_\_\_

So given  $g(x)$  \_\_\_\_\_ to find the horizontal shift, we have to factor out the 2.

Examples

Graph  $f(x) = 2\sin\left(3x - \frac{\pi}{4}\right)$

Graph  $f(x) = 3\cos\left(\pi x + \frac{\pi}{6}\right)$

How would we graph  $g(x) = -3\cos\left(\pi x + \frac{\pi}{6}\right) + 1$ ? \_\_\_\_\_

Summarizing  $f(x) = a\cos(k(x+b)) + c$        $f(x) = a\sin(k(x+b)) + c$
